

How does a microphone work?

The microphone is a device that converts sound waves into electrical signals. Microphones use the to induce a changing current from the pressure variations of sound waves. In a moving-coil microphone: potential difference The potential difference (or voltage) of a supply is a measure of the energy given to the charge carriers in a circuit.

How does a pressure microphone work?

Principle: sound moves the cone and the attached coil of wire moves in the field of a magnet. The generator effect produces a voltage which "images" the sound pressure variation - characterized as a pressure microphone. Relatively cheap and rugged. Can be easily miniaturized.

What do you need to know about a microphone?

Know that a microphone converts a sound wave of energy to an electrical energy signals. Be able to explain the structure and function of components such as the magnet,diaphragm and coil. WHAT NEXT?

What is a microphone used for?

Microphones are transducers which detect sound signals and produce an electrical image of the sound, i.e., they produce a voltage or a current which is proportional to the sound signal. The most common microphones for musical use are dynamic, ribbon, or condenser microphones.

What is a generator effect?

The generator effect produces a voltage which "images" the sound pressure variation-characterized as a pressure microphone. Relatively cheap and rugged. Can be easily miniaturized. The uniformity of response to different frequencies does not match that of the ribbon or condenser microphones.

What is a moving coil microphone?

Moving-coil microphone - A microphone that produces an electric signal from sound using the generator effect. Loudspeakers can be made by wrapping a coil of insulated wire around a paper tube attached to a paper cone,connecting the coil to a signal generator and placing the coil over a strong magnet.
